

DeamonSets

It is a process which runs in background

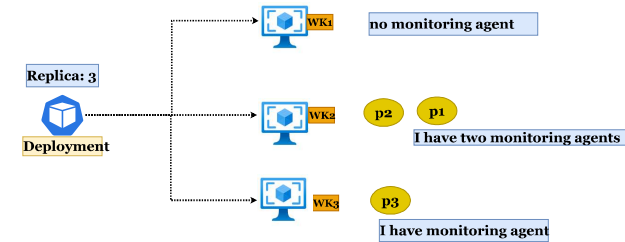

Requirement: Each pod catch only 1 node
Note: We can't guarate it ..

Use case

- 1. Configuring monitoring for my cluster
- 2. In order to achieve this I have to have one agent per node to be configured and up & running
- 3. If in case if the agent running in the machine is down then i have to ensure that no agent goes down in the servers.
- 4. If any agent goes down then we are going to loose our monitoring .

Scenario1: Monitoring deployed as deployment

Note: Since we have two pods running in wk2 we get duplicate logs shipped to the monitoring server.

Finally we can say that with deployment I cannot full fill the requirement of each one catch1 policy ...

Scenario2: Using Deamonsets
